

An energy-conserving anelastic approximation for strongly stably-stratified fluids

Loren Matilsky

February 25, 2024

1 Introduction

Abstract: When acoustic oscillations are believed to be irrelevant to the dynamics of an astrophysical fluid, it is useful to employ simplifying approximations to the equations of motion. The two most common of these (which are usually used to treat convection problem) are the Boussinesq approximation (when the background density does not significantly vary across the fluid layer) and the anelastic approximation (when the background density does vary significantly). There are many distinct forms of the anelastic approximation in the literature, and it has often been remarked that most of these do not properly conserve energy when the fluid is stable to convection. Here we show that the anelastic equations derived by Gough (1969) in fact do conserve energy for arbitrary motions of the fluid, even for strongly stratified background stratification. The key properties of these equations that allow them to conserve energy are (1) the absence of the Lantz-Braginsky-Roberts approximation in the momentum equation and (2) the inclusion of a historically neglected term in the energy equation, which allow the proper conversion between kinetic and potential energy at the correct order of the formal asymptotic expansion of the equations. We show that the scaling analysis of Gough (1969), which implicitly assumed a single typical value of the background entropy gradient, can be valid even for convective overshoot, where the entropy gradient changes from slightly unstable in the convecting region to stable (sometimes strongly so) in the overshoot region. The requirement for the anelastic equations to be valid for convective overshoot is that the buoyancy frequency be significantly less than the acoustic cutoff frequency.

The anelastic equations originally consisted of an approximation to the continuity and momentum equations, derived by assuming small thermal perturbations about a nearly adiabatically stratified hydrostatic reference atmosphere (Batchelor, 1953; Charney & Ogura, 1960). The thermodynamics of the problem thus become “linear,” in the sense that products of thermodynamic variables reduced to linear expressions in the first-order perturbations. The two key consequences of linearized thermodynamics are divergenceless mass flux (i.e., $\nabla \cdot (\bar{\rho} \mathbf{u}) \equiv 0$, where $\bar{\rho}$ is the background density and \mathbf{u} the fluid velocity; this takes the place of the $\nabla \cdot \mathbf{u} = 0$ condition from the Boussinesq approximation) and the first-order buoyancy force (associated with the first-order perturbed density and pressure) being the primary driver of the flow. (Ogura & Phillips, 1962) formalized the approximation by expanding the

equations of motion in a small parameter ϵ , representing the relative variation of potential temperature across the fluid layer, and hence the relative magnitude of the thermal perturbations. They recovered the equations of [Batchelor \(1953\)](#); [Charney & Ogura \(1960\)](#) and showed an assumption about the *time scale* of the motion was necessary, in addition to the assumption of small thermal perturbations. Namely, the dynamical time scale of the buoyantly driven flows must be $O(\epsilon^{-1/2})$ times *larger* than the sound crossing time of the region. Sound waves, which imply rapid temporal variations on the order of the sound crossing time, are thus absent from the anelastic equations, making them ideal for numerical integration, where large time steps are required to capture significant evolution of the system.

In the original asymptotic expansion of [Ogura & Phillips \(1962\)](#), the energy equation was replaced by a heat (or entropy) equation for the evolution of potential temperature, *before* non-dimensionalizing the equations. The approach of considering the entropy equation instead of the energy equation before nondimensionalization is repeated in all modern implementations of the anelastic approximation that we are aware of (e.g., [Gilman & Glatzmaier 1981](#); [Lipps & Hemler 1982](#); [Glatzmaier 1984](#); [Lantz 1992](#); [Braginsky & Roberts 1995](#); [Lantz & Fan 1999](#); [Clune et al. 1999](#); [Rogers & Glatzmaier 2005](#); [Brown et al. 2012](#); [Vasil et al. 2013](#); [Wilczyński et al. 2022](#)). The resulting energy equation is also used in all numerical codes we are aware of that utilize the anelastic equations, for example, the **ASH** code ([Brun et al., 2004](#)), the **MagIC** code ([Gastine & Wicht, 2012](#)), the **Rayleigh** code ([Featherstone & Hindman, 2016](#); [Featherstone et al., 2023](#)), the **EULAG** code ([Smolarkiewicz & Prusa, 2004](#)), and the **Dedalus** code ([Burns et al., 2020](#); [Brown et al., 2020](#)).

While nondimensionalizing the heat equation instead of the energy equation may at first appear to be an arbitrary and innocuous choice, we show in the present work that it leads to an asymptotically inconsistent set of equations that do not conserve energy when the background is stably stratified. [Gough \(1969\)](#), by contrast, took a different approach than [Ogura & Phillips \(1962\)](#) and performed a formal asymptotic expansion in ϵ while nondimensionalizing the energy equation. We now show that this equation set, which we dub the “Energy-conserving Generalized Gough” (EGG) anelastic equations, conserve energy for arbitrary fluid motions and for all hydrostatic background states (whether stably or unstably stratified).

2 The fully compressible equations

We begin by writing down the unapproximated fully compressible equations of motion for a nonrotating nonmagnetic fluid considered by [Gough \(1969\)](#). These are the continuity equation

$$\frac{\partial \rho}{\partial t} = -\nabla \cdot (\rho \mathbf{u}) \quad (1)$$

the momentum equation,

$$\frac{\partial}{\partial t}(\rho \mathbf{u}) = -\nabla \cdot (\rho \mathbf{u} \mathbf{u}) - \nabla P + \rho \mathbf{g} + \nabla \cdot \overleftrightarrow{D}, \quad (2a)$$

$$\text{where} \quad D_{ij} = \mu \left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} - \frac{2}{3}(\nabla \cdot \mathbf{u})\delta_{ij} \right), \quad (2b)$$

the energy equation,

$$\frac{\partial}{\partial t}(\rho U) + \nabla \cdot (\rho U \mathbf{u}) + P \nabla \cdot \mathbf{u} = D_{ij} \frac{\partial u_i}{\partial x_j} + Q - \nabla \cdot \mathbf{F}, \quad (3)$$

and a general equation of state,

$$U = U(P, T). \quad (4)$$

Here, t is the time, the x_i are Cartesian spatial coordinates, ρ is the density, P the pressure, T the temperature, U the internal energy per unit mass, μ the dynamic viscosity, $\mathbf{g} := -\nabla \Phi$ the gravitational acceleration field, Φ the gravitational potential, Q an internal heat source, \mathbf{F} the combined conductive and radiative heat flux. \mathbf{g} is assumed to point in the vertical direction $\hat{\mathbf{k}}$ (either the upward Cartesian direction or the radial direction), depends only on the vertical coordinate q (either the upward Cartesian coordinate x_3 or the radial coordinate r), and is time-independent (self-gravity is ignored). The symbol “ \leftrightarrow ” in the viscous stress tensor \overleftrightarrow{D} denotes a second-order tensor, as does the dyadic notation $\mathbf{u}\mathbf{u}$. The subscripts i and j (taking the values 1, 2, 3) denote vector or tensor components in any of the Cartesian spatial directions. We use the Einstein summation convention and δ_{ij} denotes the Kronecker delta.

These equations are not written in the exact form of [Gough \(1969\)](#) (and use slightly different notation) but are mathematically equivalent. Note that the left-hand side (LHS) of Equation (3) can be written in several other forms which will prove useful:

$$\frac{\partial}{\partial t}(\rho U) + \nabla \cdot (\rho U \mathbf{u}) + P \nabla \cdot \mathbf{u} = \rho \frac{DU}{Dt} - \frac{P}{\rho} \frac{D\rho}{Dt} \quad (5a)$$

$$= \rho \frac{Dh}{Dt} - \frac{DP}{Dt} \quad (5b)$$

$$= \rho T \frac{DS}{Dt}, \quad (5c)$$

where

$$\frac{D}{Dt} := \frac{\partial}{\partial t} + \mathbf{u} \cdot \nabla \quad (6)$$

is the material (or Lagrangian) derivative,

$$h := U + \frac{P}{\rho} \quad (7)$$

is the specific enthalpy, and

$$S = S(P, T) \quad (8)$$

is the specific entropy.

It will also be helpful to define the following fluid properties associated with the generalized equations of state (4) and (8): the specific heat at constant pressure,

$$C_p = C_p(P, T) := T \left(\frac{\partial S}{\partial T} \right)_P, \quad (9)$$

the squared adiabatic sound speed,

$$c_s^2 = c_s^2(P, T) := \left(\frac{\partial P}{\partial \rho} \right)_S, \quad (10)$$

and the thermal expansion coefficient,

$$\delta = \delta(P, T) := - \left(\frac{\partial \ln \rho}{\partial \ln T} \right)_P. \quad (11)$$

The first law of thermodynamics takes the following forms:

$$TdS = dU - \frac{P}{\rho^2} d\rho \quad (12a)$$

$$= dh - \frac{dP}{\rho} \quad (12b)$$

$$= C_p dT - \frac{\delta}{\rho} dP \quad (12c)$$

$$= \frac{C_p T}{\rho \delta} \left[\frac{dP}{c_s^2} - d\rho \right]. \quad (12d)$$

An equation for the evolution of kinetic energy can be formed from $\rho \mathbf{u}$ dotted into Equation (2),

$$\frac{\partial}{\partial t} \left(\frac{1}{2} \rho u^2 \right) = -\nabla \cdot \left(\frac{1}{2} \rho u^2 \mathbf{u} \right) + \mathbf{u} \cdot \nabla P - \rho \mathbf{u} \cdot \nabla \Phi + u_i \frac{\partial D_{ij}}{\partial x_j} \quad (13)$$

Equation (1) multiplied by Φ yields an equation for the evolution of potential energy,

$$\frac{\partial}{\partial t} (\rho \Phi) = -\Phi \nabla \cdot (\rho \mathbf{u}). \quad (14)$$

Adding Equations (3), (13), and (14) yields an equation for the evolution of total energy,

$$\frac{\partial}{\partial t} \left[\rho \left(\frac{1}{2} u^2 + U + \Phi \right) \right] = -\nabla \cdot \left\{ \left[\rho \left(\frac{1}{2} u^2 + U + \Phi \right) + P \right] \mathbf{u} - \mathbf{u} \cdot \overleftrightarrow{D} + \mathbf{F} \right\} + Q. \quad (15)$$

3 The anelastic approximation of Gough (1969)

We will not repeat the full asymptotic expansion in ϵ of Equations (1), (2), (3), and (4) here. Instead, we reiterate the salient assumptions in the case where the horizontally averaged reference atmosphere is time-independent and the layer depth is thicker than the typical pressure scale height (Gough (1969) also considers thin layers, in which the anelastic equations become the Boussinesq equations, and time-dependent reference atmospheres). The main assumption is that the thermodynamic perturbations from the horizontally averaged state are small, e.g.,

$$\begin{aligned} \rho &= \bar{\rho}(q) + \rho_1(x_i, t) & \text{with} & \quad \rho_1/\bar{\rho} = O(\epsilon) \ll 1, \\ P &= \bar{P}(q) + P_1(x_i, t) & \text{with} & \quad P_1/\bar{P} = O(\epsilon) \ll 1, \end{aligned} \quad (16)$$

and similarly for T , U , h , C_p , μ , δ , c_s^2 , \mathbf{F} , and Q . Here, the overbars denote horizontal averages and the “1” subscripts denote the perturbations about this average. Note that it is *not* correct to write “ $S = \bar{S}(q) + S_1(x_i, t)$ with $S_1/\bar{S} = O(\epsilon)$.” The fully compressible equations of motion contain only differences in entropy and so no meaningful absolute value of \bar{S} can be defined. Instead, we must write

$$S = \bar{S}(q) + S_1(x_i, t) \quad \text{with} \quad S_1/\bar{C}_p = O(\epsilon) \ll 1. \quad (17)$$

The second assumption is that the coordinate system can be chosen such that there is no mass flux across any horizontal surface, i.e.,

$$\overline{\rho u_i} = 0. \quad (18)$$

In a spherical system, the horizontal average would be an spherically symmetric average and the coordinates would point along the spatially varying curvilinear coordinate directions.

The characteristic length scale of variation of the fluid is assumed to be a typical value for the pressure scale height H . The flow is assumed to be buoyantly driven by the $O(\epsilon)$ thermal perturbations, i.e.,

$$|\mathbf{u}| = O(\sqrt{\epsilon \tilde{g} H}) = O(\sqrt{\epsilon \tilde{c}_s}), \quad (19)$$

where the tildes denote typical reference-state values. Thus, the squared Mach number of the flow is $O(\epsilon)$. The characteristic time scale of variation of the fluid is assumed to be advective, i.e.,

$$\left| \frac{\partial}{\partial t} \right| = O\left(\sqrt{\frac{\epsilon \tilde{g}}{H}} \right) = O\left(\sqrt{\epsilon} \frac{1}{H/\tilde{c}_s} \right). \quad (20)$$

Thus, the characteristic time scale is $O(\epsilon^{1/2} - 1/2)$ longer than the time it takes a sound wave to cross a pressure scale height.

Finally, the vertical convective heat flux (which maximally could transport an energy flux of order $\bar{\rho} \bar{T} w \Delta \bar{S}$, where $w = \hat{\mathbf{k}} \cdot \mathbf{u}$ is the vertical velocity and $\Delta \bar{S}$ is the total drop in background entropy across the convecting layer) is assumed to be limited primarily by the thermal diffusion \mathbf{F} (this will be true if the conductive heating $-\nabla \cdot \mathbf{F}$ in Equation (3) is at least as large as the viscous and internal heatings). In the case of negligible heatings (high Rayleigh number), one expects

$$\frac{\Delta \bar{S}}{\tilde{C}_p} = O(\epsilon), \quad (21)$$

i.e., the convecting layer is nearly adiabatically stratified for vigorous convection.

Once all of these scaling assumptions have been made, Equations (1), (2), (3), and (4) are nondimensionalized, each term is expanded in powers of ϵ , terms up to zeroth-order in the continuity equation and first-order in the other equations are retained, and redimension- alization then yields the anelastic equations. Note that one consequence of Equation (18) is that the horizontally averaged velocity $\bar{\mathbf{u}}$ is $O(\epsilon)$ *smaller* than the perturbed velocity \mathbf{u}_1 .

Hence, only the perturbation velocity \mathbf{u}_1 appears in the equations, and we subsequently drop the subscripts on \mathbf{u} (so that, by definition, $\bar{\mathbf{u}} \equiv 0$).

Under the anelastic approximation, the continuity equation becomes

$$\nabla \cdot (\bar{\rho} \mathbf{u}) = 0, \quad (22)$$

the momentum equation becomes

$$\frac{\partial}{\partial t}(\bar{\rho} \mathbf{u}) = -\nabla \cdot (\bar{\rho} \mathbf{u} \mathbf{u}) - \nabla P_1 + \rho_1 \mathbf{g} + \nabla \cdot \overleftrightarrow{D} + [-\nabla \bar{P} + \bar{\rho} \mathbf{g}], \quad (23a)$$

$$\text{where now} \quad D_{ij} = \bar{\mu} \left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} - \frac{2}{3}(\nabla \cdot \mathbf{u})\delta_{ij} \right), \quad (23b)$$

the energy equation becomes

$$\begin{aligned} \bar{\rho} \bar{C}_p \frac{\partial T_1}{\partial t} - \bar{\delta} \frac{\partial P_1}{\partial t} = & -\bar{\rho} \mathbf{u} \cdot \left(\nabla h_1 - \frac{1}{\bar{\rho}} \nabla P_1 \right) - \bar{\rho} \bar{T} \mathbf{u} \cdot \nabla \bar{S} \\ & D_{ij} \frac{\partial u_i}{\partial x_j} + Q_1 - \nabla \cdot \mathbf{F}_1 - \rho_1 \mathbf{u} \cdot \mathbf{g} - \bar{T}(\rho_1 \mathbf{u} - \bar{\rho}_1 \mathbf{u}) \cdot \nabla \bar{S} \\ & + [\bar{Q} - \nabla \cdot \mathbf{F}], \end{aligned} \quad (24)$$

and the linearized equation of state becomes

$$\bar{T} S_1 = \bar{C}_p T_1 - \frac{\bar{\delta}}{\bar{\rho}} P_1 \quad (25a)$$

$$= U_1 - \frac{\bar{P}}{\bar{\rho}^2} \rho_1 \quad (25b)$$

$$= h_1 - \frac{P_1}{\rho} \quad (25c)$$

$$= \frac{\bar{C}_p \bar{T}}{\bar{\delta} \bar{\rho}} \left[\frac{P_1}{\bar{c}_s^2} - \rho_1 \right]. \quad (25d)$$

Note that from Equation (25a), the LHS of Equation (24) can be written in terms of the entropy S_1 ,

$$\bar{\rho} \bar{C}_p \frac{\partial T_1}{\partial t} - \bar{\delta} \frac{\partial P_1}{\partial t} = \bar{\rho} \bar{T} \frac{\partial S_1}{\partial t}. \quad (26)$$

Again, these equations are not in the identical form of Gough (1969) but are mathematically equivalent. Note that Gough (1969) expands the mass flux (or equivalently, the momentum density) $\mathbf{m} = \rho \mathbf{u}$ in ϵ rather than the velocity \mathbf{u} . Because of the zero mean mass flux condition (18), we can write

$$\mathbf{m} = \bar{\rho} \mathbf{u} + \rho_1 \mathbf{u} - \bar{\rho}_1 \mathbf{u} + O(\epsilon^2). \quad (27)$$

The latter two terms are $O(\epsilon)$. In most cases, we can thus write $\mathbf{m} \approx \bar{\rho} \mathbf{u}$ to translate from Gough (1969) to the current notation (which uses \mathbf{u} as the field variable), except when

multiplying by potentially $O(0)$ quantities like $\nabla \bar{S}$. We have used Equation (27) to yield the term $-\bar{T}(\rho_1 \mathbf{u} - \bar{\rho}_1 \bar{\mathbf{u}}) \cdot \nabla \bar{S}$ in Equation (24).

The differentials in Equation (12) can be converted into gradients (e.g., $T \nabla S = \nabla h - \nabla P / \rho$) and the horizontally averaged form of these relations yields

$$\bar{T} \nabla \bar{S} = \bar{C}_p \nabla \bar{T} - \frac{\bar{\delta}}{\bar{\rho}} \nabla \bar{P} + O(\epsilon^2) \quad (28a)$$

$$= \frac{\bar{C}_p \bar{T}}{\bar{\delta} \bar{\rho}} \left[\frac{\nabla \bar{P}}{c_s^2} - \nabla \bar{\rho} \right] + O(\epsilon^2). \quad (28b)$$

Note that Gough (1969) uses the superadiabatic temperature gradient

$$\beta := -\frac{\bar{T}}{\bar{C}_p} \hat{\mathbf{k}} \cdot \nabla \bar{S} \quad (29)$$

in place of $\nabla \bar{S}$.

The zeroth order (horizontally averaged) parts of Equations (23) and (24) satisfy

$$-\nabla \bar{P} + \bar{\rho} \mathbf{g} = \nabla(\bar{\rho} w^2) \quad (30)$$

and

$$\bar{Q} - \nabla \cdot \bar{\mathbf{F}} = \overline{\bar{\rho} \mathbf{u} \cdot \left(\nabla h_1 - \frac{1}{\bar{\rho}} \nabla P_1 \right)} + \mathbf{g} \cdot \overline{\bar{\rho}_1 \bar{\mathbf{u}}} - \overline{D_{ij} \frac{\partial u_i}{\partial x_j}} \quad (31)$$

In each of Equations (30) and (31), each term on the right-hand side (RHS) is $O(\epsilon)$ compared to each term on the LHS. In particular, we can approximate

$$\nabla \bar{P} \approx \bar{\rho} \mathbf{g} \quad (32)$$

in terms that are already of first-order in ϵ . Dotting \mathbf{u} into Equation (23a) yields the anelastic kinetic energy equation,

$$\frac{\partial}{\partial t} \left(\frac{1}{2} \bar{\rho} u^2 \right) = -\nabla \cdot \left(\frac{1}{2} \bar{\rho} u^2 \mathbf{u} \right) - \mathbf{u} \cdot \nabla P_1 + \rho_1 \mathbf{u} \cdot \mathbf{g} + u_i \frac{\partial D_{ij}}{\partial x_j} + \mathbf{u} \cdot \nabla(\bar{\rho} w^2), \quad (33)$$

where we have used Equation (30) to write the work due to the “turbulent pressure,” $\mathbf{u} \cdot \nabla(\bar{\rho} w^2)$. Using Equations (22) and (25) as needed and then adding Equations (24) and (33) yields the anelastic total energy equation,

$$\begin{aligned} \frac{\partial}{\partial t} \left[\bar{\rho} \left(\frac{1}{2} u^2 + \bar{T} S_1 \right) \right] = & -\nabla \cdot \left\{ \left[\bar{\rho} \left(\frac{1}{2} u^2 + \bar{T} S_1 \right) + P_1 \right] \mathbf{u} - \mathbf{u} \cdot \overleftrightarrow{D} + \bar{\mathbf{F}} + \mathbf{F}_1 \right\} \\ & + \bar{Q} + Q_1 + \left[-\bar{\rho} \bar{T} \mathbf{u} \cdot \nabla \bar{S} + \mathbf{u} \cdot \nabla(\bar{\rho} w^2) - \bar{T}(\rho_1 \mathbf{u} - \bar{\rho}_1 \bar{\mathbf{u}}) \cdot \nabla \bar{S} \right] \end{aligned} \quad (34)$$

Note that by definition,

$$\bar{\mathbf{u}} = 0, \quad (35)$$

so that each of the rightmost terms in brackets in Equation (34) cannot transport any net energy across the layer. The internal heating terms $\bar{Q} + Q_1$ are assumed “accounted for,” since in modern anelastic codes, they are typically inputs to drive convection. Thus, Equation (34) shows that the total energy integrated over the volume V of the layer,

$$E_{\text{tot}} := \int_V \bar{\rho} \left(\frac{1}{2} u^2 + \bar{T} S_1 \right) dV \quad (36)$$

is conserved if the various fluxes in the divergence on the RHS of Equation (34) vanish on the boundaries. This conservation holds for arbitrary fluid motions that obey the anelastic equations ((22), (23), (24), and (25)) and for arbitrary magnitudes of $|\nabla \bar{S}|$. Whether the approximation remains *consistent*, however, *does* depend on the magnitude of $|\nabla \bar{S}|$.

Note that from Equation (25b), the perturbed internal energy is $U_1 = \bar{T} S_1 + (\bar{P}/\bar{\rho}^2) \rho_1$. The latter compressive term is thus eliminated under the anelastic approximation and we instead identify $\bar{T} S_1$ with the internal energy. The disappearance of the compressive term, which was called the “elastic energy” in Eckart & Ferris (1956), is the origin of the term “anelastic,” coined by Jule Charney (see Ogura & Phillips 1962). The potential energy term also disappears, which is a direct consequence of the assumption of zero mean mass flux, Equation (18).

4 The Gough (1969) equations in more familiar form

Modern anelastic codes typically write the equations using the perturbed pressure and entropy (P_1 and S_1) in place the quantities T_1 , P_1 , ρ_1 , and h_1 that appear in Equations (23) and (30). We can convert using Equations (25) and (28) and the approximation (32). In the momentum equation, we find

$$-\nabla P_1 + \rho_1 \mathbf{g} = -\bar{\rho} \nabla \left(\frac{P_1}{\bar{\rho}} \right) - \bar{\delta} \bar{\rho} \left(\frac{S_1}{\bar{C}_p} \right) \mathbf{g} + \frac{\bar{\delta} \bar{\rho}}{\bar{C}_p} \left(\frac{P_1}{\bar{\rho}} \right) \nabla \bar{S}. \quad (37)$$

In the energy equation, we find

$$-\bar{\rho} \mathbf{u} \cdot \left(\nabla h_1 - \frac{1}{\bar{\rho}} \nabla P_1 \right) = -\bar{\rho} \bar{T} \mathbf{u} \cdot \nabla S_1 - \bar{\rho} S_1 \mathbf{u} \cdot \nabla \bar{T} + \left(\frac{P_1}{\bar{\rho}} \right) \mathbf{u} \cdot \nabla S_1. \quad (38)$$

Using Equations (25), (28), and (32), we compute, with some effort,

$$-\bar{\rho} S_1 \mathbf{u} \cdot \nabla \bar{T} + \left(\frac{P_1}{\bar{\rho}} \right) \mathbf{u} \cdot \nabla S_1 - \rho_1 \mathbf{u} \cdot \mathbf{g} = -\bar{\rho} T_1 \mathbf{u} \cdot \nabla \bar{S} + O(\epsilon^2). \quad (39)$$

Using Equation (37) in Equation (23), and then Equations (26), (38), and (39) in Equation (24), we find

$$\begin{aligned} \frac{\partial}{\partial t} (\bar{\rho} \mathbf{u}) = & -\nabla \cdot (\bar{\rho} \mathbf{u} \mathbf{u}) - \bar{\rho} \nabla \left(\frac{P_1}{\bar{\rho}} \right) - \bar{\delta} \bar{\rho} \left(\frac{S_1}{\bar{C}_p} \right) \mathbf{g} + \underbrace{\frac{\bar{\delta} P_1}{\bar{C}_p} \nabla \bar{S}}_{:= \mathbf{f}_{\text{NLBR}}} + \nabla \cdot \overleftrightarrow{D} \\ & + [-\nabla \bar{P} + \bar{\rho} \mathbf{g}], \end{aligned} \quad (40)$$

and

$$\begin{aligned} \bar{\rho} \bar{T} \frac{\partial S_1}{\partial t} = & -\bar{\rho} \bar{T} \mathbf{u} \cdot \nabla S_1 - \bar{\rho} \bar{T} \mathbf{u} \cdot \nabla \bar{S} - \underbrace{\bar{\rho} T_1 \mathbf{u} \cdot \nabla \bar{S}}_{:=Q_{\text{NLBR}}} + D_{ij} \frac{\partial u_i}{\partial x_j} + Q_1 - \nabla \cdot \mathbf{F}_1 \\ & + [\bar{Q} - \nabla \cdot \bar{\mathbf{F}} - \bar{T}(\rho_1 \mathbf{u} - \bar{\rho}_1 \bar{\mathbf{u}}) \cdot \nabla \bar{S}], \end{aligned} \quad (41a)$$

$$\text{where} \quad \rho_1 = \frac{P_1}{c_s^2} - \frac{\bar{\delta} \bar{\rho}}{\bar{C}_p} \quad (41b)$$

$$\text{and} \quad T_1 = \frac{\bar{T} S_1}{\bar{C}_p} + \frac{\bar{\delta} P_1}{\bar{\rho} \bar{C}_p}. \quad (41c)$$

The final terms in brackets in these equations may be dropped without affecting energy conservation, since they do not transport any net energy. However, dropping them still may still make the equations an asymptotically inconsistent approximation to the true fully compressible motion. The essential terms required for energy conservation when $\nabla \bar{S} \neq 0$ are the “non-LBR” force density

$$\mathbf{f}_{\text{NLBR}} := \frac{\bar{\delta} P_1}{\bar{C}_p} \nabla \bar{S} \quad (42)$$

and the “non-LBR” heating

$$Q_{\text{NLBR}} := -\bar{\rho} T_1 \mathbf{u} \cdot \nabla \bar{S}. \quad (43)$$

Both these terms vanish for an adiabatic background state (where $\nabla \bar{S} = 0$), which is expected for a fully (and sufficiently vigorously) convecting layer. Neglecting \mathbf{f}_{NLBR} was first done independently by [Lantz \(1992\)](#) and [Braginsky & Roberts \(1995\)](#) and is referred as the “Lantz-Braginsky-Roberts” (LBR) approximation. The term Q_{LBR} in the energy equation, which was implicitly contained in the equations of [Gough \(1969\)](#), seems to be absent in the other forms of the anelastic equations currently in use and its neglect seems to have not been explicitly considered.

5 The equivalence of horizontally averaged atmospheres to fixed reference atmospheres

In the formalism of [Gough \(1969\)](#), the horizontally averaged atmosphere, referenced by the overbars, cannot be specified a priori because it depends on the ultimate flow via Equations (30) and (31). Many anelastic numerical codes (e.g., the [Rayleigh](#), [EULAG](#), and [MagIC](#) codes) instead treat the background state as a fixed hydrostatic “reference” state and let the perturbations in S and P develop small but nonzero horizontally averaged perturbations about the reference state. Some codes (e.g., the [ASH](#) code) alternatively solve for the nonspherical perturbations directly, retaining bracketed terms like the ones in Equations (23) and (24). As we now show, these two approaches are exactly equivalent to the order of the approximation, provided that the thermal variables do not wander by more than $O(\epsilon)$ away from their preordained reference state values.

Our approach is to define the horizontally averaged profiles as the sum of the preordained horizontally symmetric reference-state value (denoted by a tilde) and a horizontally symmetric deviation (denoted by a hat):

$$\overline{P} = \tilde{P} + \hat{P}, \quad (44)$$

$$\overline{\rho} = \tilde{\rho} + \hat{\rho}, \quad (45)$$

$$\overline{S} = \tilde{S} + \hat{S}, \quad (46)$$

etc., where we assume (apart from the entropy) that the hatted means are $O(\epsilon)$ compared to the reference-state means. We also assume that the reference state is hydrostatic,

$$\nabla \tilde{P} = \tilde{\rho} \mathbf{g}. \quad (47)$$

We denote the deviations from the reference state by primes and note that

$$P' := P - \tilde{P} = P_1 + \hat{P}, \quad (48)$$

$$\rho' := \rho - \tilde{\rho} = \rho_1 + \hat{\rho}, \quad (49)$$

$$S' := S - \tilde{S} = S_1 + \hat{S}, \quad (50)$$

etc. The primed quantities (except for the entropy) are always $O(\epsilon)$ compared to the reference-state means. The linearized equation of state for the primed quantities is exactly analogous to Equation (25),

$$\tilde{T}S' = \tilde{C}_p T' - \frac{\tilde{\delta}}{\tilde{\rho}} P', \quad (51a)$$

$$= U' - \frac{\tilde{P}}{\tilde{\rho}^2} \rho' \quad (51b)$$

$$= h' - \frac{P'}{\tilde{\rho}} \quad (51c)$$

$$= \frac{\tilde{C}_p \tilde{T}}{\tilde{\delta} \tilde{\rho}} \left[\frac{P'}{\tilde{c}_s^2} - \hat{\rho} \right]. \quad (51d)$$

as is the linearized equation of state for the hatted quantities. We further assume that reference state is defined to satisfy an equation analogous to Equation (28),

$$\tilde{T} \nabla \tilde{S} = \tilde{C}_p \nabla \tilde{T} - \frac{\tilde{\delta}}{\tilde{\rho}} \nabla \tilde{P} \quad (52a)$$

$$= \frac{\tilde{C}_p \tilde{T}}{\tilde{\delta} \tilde{\rho}} \left[\frac{\nabla \tilde{P}}{\tilde{c}_s^2} - \nabla \tilde{\rho} \right]. \quad (52b)$$

To zeroth order in ϵ , Equation (22) becomes simply

$$\nabla \cdot (\bar{\rho} \mathbf{u}) \equiv 0 \quad (53)$$

Because the RHS of Equations (23) is $O(\epsilon)$ compared to the LHS's we can write (also using Equation (47))

$$\begin{aligned} [-\nabla \bar{P} + \bar{\rho} \mathbf{g}] &= -\nabla \hat{P} + \hat{\rho} \mathbf{g} \\ &= -\tilde{\rho} \nabla \left(\frac{\hat{P}}{\tilde{\rho}} \right) - \tilde{\delta} \tilde{\rho} \left(\frac{\hat{S}}{\tilde{C}_p} \right) \mathbf{g} + \frac{\tilde{\delta} \tilde{\rho}}{\tilde{C}_p} \left(\frac{\hat{P}}{\tilde{\rho}} \right) \nabla \tilde{S}. \end{aligned} \quad (54)$$

Note that the non-LBR force density from Equation (42) is only significant when $\nabla \bar{S}$ is large (in which case $\nabla \bar{S} = \nabla \tilde{S} + O(\epsilon)$), otherwise it is $O(\epsilon^2)$. For all magnitudes of $|\nabla \bar{S}|$, we can thus write

$$\mathbf{f}_{\text{NLBR}} = \frac{\bar{\delta} P_1}{\tilde{C}_p} \nabla \tilde{S} + O(\epsilon^2) \quad (55)$$

Using Equations (54) and (55) and noting that all terms in Equation (40) are of $O(\epsilon)$ (so that we can replace overbars with tildes), we find

$$\frac{\partial}{\partial t}(\tilde{\rho} \mathbf{u}) = -\nabla \cdot (\tilde{\rho} \mathbf{u} \mathbf{u}) - \tilde{\rho} \nabla \left(\frac{P'}{\tilde{\rho}} \right) - \tilde{\delta} \tilde{\rho} \left(\frac{S'}{\tilde{C}_p} \right) \mathbf{g} + \frac{\tilde{\delta} P'}{\tilde{C}_p} \nabla \tilde{S} + \nabla \cdot \overleftarrow{D}, \quad (56a)$$

$$\text{where now} \quad D_{ij} = \tilde{\mu} \left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} - \frac{2}{3} (\nabla \cdot \mathbf{u}) \delta_{ij} \right), \quad (56b)$$

In the energy equation (41), we write

$$\tilde{Q} - \nabla \cdot \tilde{\mathbf{F}} := -\tilde{\rho} \tilde{T} \frac{\partial \hat{S}}{\partial t}. \quad (57)$$

Note that this is simply a *definition* for $\partial \hat{S} / \partial t$. The anelastic equations of Gough (1969) do not specify \hat{S} explicitly, the only requirement being (implicitly through the equation of state) the satisfaction of Equation (30).

Equation (27) can be additionally written

$$\bar{\rho} \mathbf{u} + \rho_1 \mathbf{u} - \bar{\rho}_1 \bar{\mathbf{u}} = \tilde{\rho} \mathbf{u} + \rho' \mathbf{u} - \bar{\rho}' \bar{\mathbf{u}} + O(\epsilon^2). \quad (58)$$

We finally write

$$Q_{\text{NLBR}} = \tilde{\rho} T_1 \mathbf{u} \cdot \nabla \tilde{S} + O(\epsilon^2) \quad (59)$$

and

$$-\bar{\rho} \bar{T} \mathbf{u} \cdot \nabla S_1 - \bar{\rho} \bar{T} \mathbf{u} \cdot \nabla \bar{S} = -\tilde{\rho} \tilde{T} \mathbf{u} \cdot \nabla S' - \tilde{T}(\bar{\rho} \mathbf{u}) \cdot \nabla \tilde{S} - \tilde{\rho} \hat{T} \mathbf{u} \cdot \nabla \tilde{S}. \quad (60)$$

Plugging in Equations (57) through (60) into Equation (41) thus yields

$$\begin{aligned} \tilde{\rho} \tilde{T} \frac{\partial S'}{\partial t} &= -\tilde{\rho} \tilde{T} \mathbf{u} \cdot \nabla S' - \tilde{\rho} \tilde{T} \mathbf{u} \cdot \nabla \tilde{S} - \tilde{\rho} T' \mathbf{u} \cdot \nabla \tilde{S} + D_{ij} \frac{\partial u_i}{\partial x_j} + Q' - \nabla \cdot \tilde{\mathbf{F}}' \\ &\quad - \tilde{T}(\rho' \mathbf{u} - \bar{\rho}' \bar{\mathbf{u}}) \cdot \nabla \tilde{S}, \end{aligned} \quad (61a)$$

$$\text{where} \quad \rho' = \frac{P'}{\tilde{c}_s^2} - \frac{\tilde{\delta} \tilde{\rho} S'}{\tilde{C}_p} \quad (61b)$$

$$\text{and} \quad T' = \frac{\tilde{T} S'}{\tilde{C}_p} + \frac{\tilde{\delta} P'}{\tilde{\rho} \tilde{C}_p}. \quad (61c)$$

Taking the spherical means of Equations (62b) and (62c) and using Equations (47) and Equations (57) then recovers the mean momentum and energy equations (30) and (31). The formulation with fixed reference states (Equations (62a), (62b) and (62c)) is thus seen to be asymptotically equivalent to the formulation with horizontally averaged background states (Equations (22), (40), and (41), combined with Equations (30) and (31)).

6 The Energy-conserving Generalized Gough (EGG) anelastic approximation

To arrive at the final form of the equations, we make one final argument: that the last term in Equation (61a) is negligible. It has zero horizontal mean and therefore cannot affect the net transport of energy. Pointwise, it is always much smaller than the background advection term $-\tilde{\rho}\tilde{T}\mathbf{u} \cdot \nabla \tilde{S}$. It therefore seems safe to neglect.

The final equations, representing what we call the Energy-conserving Generalized Gough (EGG) anelastic approximation, are thus

$$\begin{aligned} \nabla \cdot (\tilde{\rho}\mathbf{u}) &\equiv 0, & (62a) \\ \frac{\partial}{\partial t}(\tilde{\rho}\mathbf{u}) &= -\nabla \cdot (\tilde{\rho}\mathbf{u}\mathbf{u}) - \tilde{\rho}\nabla \left(\frac{P'}{\tilde{\rho}} \right) - \tilde{\delta}\tilde{\rho} \left(\frac{S'}{\tilde{C}_p} \right) \mathbf{g} + \frac{\tilde{\delta}P'}{\tilde{C}_p} \nabla \tilde{S} + \nabla \cdot \overleftrightarrow{D}, & (62b) \\ \text{and} \quad \tilde{\rho}\tilde{T} \frac{\partial S'}{\partial t} &= -\tilde{\rho}\tilde{T}\mathbf{u} \cdot \nabla S' - \tilde{\rho}\tilde{T}\mathbf{u} \cdot \nabla \tilde{S} - \left(\frac{\tilde{T}S'}{\tilde{C}_p} + \frac{\tilde{\delta}P'}{\tilde{\rho}\tilde{C}_p} \right) \tilde{\rho}\mathbf{u} \cdot \nabla \tilde{S} \\ &\quad + D_{ij} \frac{\partial u_i}{\partial x_j} + Q' - \nabla \cdot \mathbf{F}', & (62c) \end{aligned}$$

where \overleftrightarrow{D} is defined in Equation (56b) and it is additionally assumed that the reference state satisfies the hydrostatic condition (47) and the first law of thermodynamics in gradient form, Equation (52).

The EGG kinetic energy equation, derived from \mathbf{u} dotted into Equation (62b), is

$$\frac{\partial}{\partial t} \left(\frac{1}{2} \tilde{\rho} u^2 \right) = -\nabla \cdot \left(\frac{1}{2} \tilde{\rho} u^2 \mathbf{u} \right) - \mathbf{u} \cdot \nabla P' - \tilde{\delta}\tilde{\rho} \left(\frac{S'}{\tilde{C}_p} \right) \mathbf{u} \cdot \mathbf{g} + \frac{\tilde{\delta}P'}{\tilde{C}_p} \mathbf{u} \cdot \nabla \tilde{S} + u_i \frac{\partial D_{ij}}{\partial x_j}, \quad (63)$$

Adding Equations (62c) and (63) yields the EGG total energy equation,

$$\begin{aligned} \frac{\partial}{\partial t} \left[\tilde{\rho} \left(\frac{1}{2} u^2 + \tilde{T}S' \right) \right] &= -\nabla \cdot \left\{ \left[\tilde{\rho} \left(\frac{1}{2} u^2 + \tilde{T}S' \right) + P' \right] \mathbf{u} - \mathbf{u} \cdot \overleftrightarrow{D} + \tilde{\mathbf{F}} + \mathbf{F}' \right\} \\ &\quad + Q' - \tilde{\rho}\tilde{T}\mathbf{u} \cdot \nabla \tilde{S}. \end{aligned} \quad (64)$$

Again using condition (35), the integration of Equation (64) yields conservation of total energy,

$$\tilde{E}_{\text{tot}} := \int_V \tilde{\rho} \left(\frac{1}{2} u^2 + \tilde{T}S' \right) dV = \text{constant}, \quad (65)$$

which mathematically holds for arbitrary fluid motion obeying Equations (62) and for all magnitudes of $|\nabla \bar{S}|$.

Note that in practice when simulating stiff systems (large $|\nabla \tilde{S}|$) numerically (e.g., [Guerero et al. 2016](#); [Matilsky et al. 2022](#); ?)
